Unit 2, S12, SLO1 - Implementation of Doubly Linked Lists

1. A doubly linked list node typically contains data, a pointer to the next node, and a pointer to the __ node.

Answer: previous

2. The structure of a doubly linked list node in C often uses the keyword __.

Answer: struct

3. In C, to create a node dynamically, we use the function __.

Answer: malloc()

4. The first node of a doubly linked list is called the __.

Answer: head / START

5. To insert a node at the beginning, the new node's next pointer should point to the __ node.

Answer: head (current first)

6. When inserting at the beginning, the previous pointer of the old head should point to the __ node.

Answer: new

7. To insert a node at the end, we must traverse the list until we find the node whose next is __.

Answer: NULL

8. While inserting at the end, the new node's previous pointer should point to the __ node.

Answer: last (tail / PTR)

9. To delete the first node, we move the head pointer to the __ node.

Answer: next (second)

10. When deleting the first node, the new head's previous pointer must be set to __.

Answer: NULL
